

Description:

A time series consisting of stock prices spanning over a period of three months is given.

1. Short-term Forecasting: Use the adjusted exponential smoothing method to forecast its value for the next period.
2. Calculate the MAPE (Mean Absolute percentage Error) of this forecast and investigate the values of the parameters (smoothing and trend parameters respectively) that yield the most accurate forecast.
3. Long-term Forecasting: Use one or more trend-based methods to forecast the value of the time series during the future periods. Next calculate the MAPE of your forecast to assess its accuracy.
